Fever

Medication Info

Fever is a common symptom resulting from the body's response to infection, inflammation, or other physiological processes. Various medications can help reduce fever, with both over-the-counter (OTC) and prescribed options available.

1. Acetaminophen (Tylenol): This is a widely used, non-prescription pain reliever and fever reducer. It works by inhibiting the production of pyridoxine (vitamin B6) within the liver, thereby reducing fever without causing liver damage. Acetaminophen is generally preferred for those with pre-existing liver conditions or those taking other medications that may affect liver function.
2. Ibuprofen (Advil, Motrin): Ibuprofen is a non-prescription anti-inflammatory medication that also has fever-reducing properties
